## U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

## PUBLIC HEALTH SERVICE

## AN OUTBREAK OF FOOD POISONING LITTLE ROCK, ARKANSAS

An outbreak of diarrheal illness affecting two public schools in Little Rock was reported to the Arkansas State Board of Health on Tuesday, October 19. The outbreak followed a luncheon on October 6, cooked in one school kitchen and served in the cafeterias of the two schools involved. Epidemiological investigations by the Little Rock City Health Department indicated that the vehicle of infection was probably turkey-a-la-king. Cultures from turkey breast left over from the meal later yielded three serotypes of Clostridium perfringens.

There are 36 public schools in Little Rock and all participate in a Federal Government-sponsored school

lunch program. The cafeterias of these schools all have the same menu each day. The two public schools affected served turkey-a-la-king on October 6 prepared from their allotment of four USDA graded and inspected turkeys. The turkey dish was served to approximately 301 children and teachers at the two schools, one of which has an approximate registered total of 800 children, the other, 58. The (Continued on page 386)

Total	60	34	34	57	

<sup>\*</sup>Information on students was obtained from teachers and absentee lists.

The illness was sudden in onset and characterized by acute abdominal pain followed by diarrhea; nausea was marked in the majority of cases but little vomiting occurred. There were no fatalities and none of the patients required hospitalization. However, 20.7 percent of those affected were ill enough to be absent from school the next day. The incubation period of the illness ranged from  $3\frac{1}{2}$  to  $13\frac{1}{2}$  hours with an average of 7.8 hours. The duration of

the illness averaged 15 hours with a range from 1 to 36 hours.

Epidemiological investigations by the City Health Department revealed that an allotment of four frozen turkeys was received at the larger school kitchen on the morning of Monday, October 4. The next morning the turkeys were cooked at 350°F for 4 to 5 hours, cooled at room temperature, and placed overnight in a milk cooler which maintains a temperature of about 40°F. On Wednesday, October 6, the turkey meat was diced and added to a broth of peas, carrots and onions. The food was then heated, but not boiled, for 30 minutes. Thereafter, the turkey-a-la-king was kept warm on steam tables at the larger school during the three lunch periods from 11:15 a.m. through 1:00 p.m. The food for the smaller school was transported by private auto to that school and served shortly after arrival there.

Laboratory investigations of the left-over turkey meat at the Arkansas State Health Department Laboratory and at the CDC have yielded cultures of *Clostridium perfringens* in which there were three separate serotypes. One serotype has been identified as Hobbs 13 but the other two were non-typable.

The State Sanitarians have inspected the school kitchens frequently in the past and pointed out the inadequacy of storage space for frozen meats and other perishable foods. Since this outbreak, new and effective refrigeration equipment has been installed. Other remedial measures have included a series of lectures on kitchen hygiene to all personnel handling food.

(Reported by Dr. J. T. Herron, State Health Officer, and Dr. William L. Bunch, Jr., Acting Director, Communicable Disease Control, Arkansas State Board of Health; Dr. Mason C. Lawson, Director, and Mr. James M. Cairns, Sanitarian, Little Rock City Health Department; and an EIS Officer.)

# EPIDEMIOLOGIC NOTES AND REPORTS DIPHTHERIA IN A GROUP OF INDIAN FAMILIES Douglas County, Nebraska

On September 18, 1965, in Omaha, Nebraska, a physician saw a 3-year-old Indian child who was not seriously ill but was suffering from a bloody nasal discharge. The following day the Omaha-Douglas County Health Department Laboratory reported a presumptive isolation of Corynebacterium diphtheriae from the child. Swabs were then immediately obtained from nine household contacts in the child's home.

Subsequent laboratory studies yielded isolates of virulent *C. diphtheriae* from nasal smears taken from the child, his father, and two siblings. During the following week, 42 additional contacts in 11 closely associated neighboring families were investigated and non-virulent *C. diphtheriae* were isolated from 3 of these contacts.

The index case and the six positive contacts were given penicillin therapy over a 10-day period. Repeat

<sup>\*\*</sup>Three servings of lunch at School I.

cultures on October 12 showed that the patient and his two sibling contacts were still harboring virulent diphtheria organisms; by then all other contacts were negative.

Following a subsequent 7-day course of erythromycin, two consecutive swabs from each of the two siblings proved to be negative on culture. The index case had been fatally injured by a fall several days before the final cultures were obtained from the two siblings. Accordingly a repeat culture was not obtained.

Of the total group of 51 persons involved, just over 50 percent gave a history of adequate immunization against diphtheria. Among the seven individuals who yielded positive cultures for *C. diphtheriae*, the immunization status is shown in Table 2.

On October 2 and 3 all individuals in the family groups concerned received boosterimmunizations against diphtheria, tetanus and poliomyelitis; children under 6 years of age were also given pertussis vaccine.

Table 2
DIPHTHERIA IN A GROUP OF INDIAN FAMILIES
Omaha, Nebraska

Case	Age	Relation- ship	Immunization	Laboratory
lndex	3 years	_	None	Virulent
2	4 years	Sibling	Primary series*	Virulent
3	11 months	Sibling	None	Virulent
4	28 years	Father	Primary series*	Virulent
5	34 years	Aunt	Primary series	Non-virulent
6	4 years	Contact	Full	Non-virulent
7	26 years	Contact	Full	Non-virulent

<sup>\*</sup>No booster followed these primary series.

(Reported by Dr. E.D. Lyman, Health Director; Miss Beatrice Adams, Director of Preventable Disease Control; Mr. Matthew Severin, Laboratory Director, all of the Omaha-Douglas County Health Department, Nebraska; and an EIS Officer.)

#### ARBOVIRUS ENCEPHALITIS - 1965

#### Eastern Equine Encephalitis - New Jersey and Delaware

The seventh confirmed human case of Eastern equine encephalitis in the United States during 1965 has been reported from New Jersey. Occurring in Cape May County, this is the first and only serologically confirmed human case in New Jersey this year. The patient is a 60-year-old woman who became ill on October 9 with manifestations of severe encephalitis. She is now improving slowly but there is evidence of permanent damage to the central nervous system.

Between September 5 and October 8 there were five confirmed cases of EEE in horses in New Jersey and during the same period the virus was recovered from a pheasant flock in the same area. Across the border in Delaware, EEE virus was also recovered from three horses between September 22 and October 11.

An important and significant complementary finding this year in New Jersey has been the recovery of EEE virus from two pools of *Aedes solicitans* on September 14 and 29. Prior to September there had been numerous isolations of EEE virus from pools of *Culiseta melanura* without any cases of human encephalitis appearing. It was only after the recovery of virus from *Aedes solicitans* that a human case of EEE occurred.

This is the first time that EEE virus has been isolated from *Aedes solicitans* although during the 1959 epidemic of EEE there was presumptive evidence that Aedes solicitans was a vector of the disease to humans. St. Louis Encephalitis - New Jersey

There have also been two human cases of St. Louis encephalitis in New Jersey with onsets of illness on September 19 and October 4 respectively. The first patient was a woman of 44 years who developed convulsions, high fever, headache, drowsiness, stuttering speech and tremor. The second patient was a man aged 41 years who complained of fever, vague myalgia, headache, mental confusion and vomiting. Both patients reside in Burlington County and both have made a good recovery from the illness. The laboratory confirmation of St. Louis encephalitis is based on the examination of single specimens of sera, from each of the patients, which showed high titers for SLE in hemoagglutination inhibition and neutralization tests.

(Reported by Dr. William J. Dougherty, Director of Preventable Disease Control Programs, New Jersey State Department of Health; Dr. Martin Goldfield, Director, and Drs. Oscar Susman and Ronald Altman of the New Jersey State Laboratories; Dr. Edward F. Gliwa, Deputy State Health Officer, Delaware State Board of Health; and the Arbovirus Unit of the Laboratory Branch of CDC.)

(Epidemiologic Notes and Reports continued on page 392)

## EPIDEMIOLOGIC NOTES AND REPORTS (Continued) PLAGUE - Shasta County, California

Field studies, following the case of human plague in Viola, Shasta County, California, reported in the MMWR, Vol. 14, No. 38, have confirmed the presence of plague in squirrels in this area. Pasteurella pestis has been isolated from the tissues of a recently dead Citellus beecheyi found 250 yards south of the home of the 5-year-old boy who developed plague in September. Two other rodent carcasses which were too decomposed for species identification were also recovered from within a mile radius of the boy's home. Bone marrow scrapings from these specimens yielded presumptive positive findings for plague, using the fluorescent antibody technique. Two pools of fleas, Diamanus montanus, obtained from animals and burrows in the same area have also been proved, by animal inoculation, to be positive for plague.

Serological studies were carried out on sera obtained from the boy's parents, his two playmates, the boy's pet dog and the playmates' dog. Only one serum, that from the boy's pet dog, gave a positive hemoagglutination inhibition test with a titer of 1:32.

(Reported by Dr. Henry Renteln, Bureau of Communicable Diseases, and Mr. Keith Murray, Bureau of Vector Control of the California State Health Department; the San Francisco Field Station of CDC; and an EIS Officer.)

ERRATUM, Vol. 14, No. 43, p. 371:

#### Summory of Reported Coses of Infectious Syphilis

The U.S. total of cases of infectious syphilis for September 1965 should be recorded as 1,914 cases and not 1,194 cases.

THE MORBIOLTY AND MORTALITY WEEKLY REPORT, WITH A CIRCULATION OF 14,000, IS PUBLISHED AT THE COMMUNICABLE DISEASE CENTER, ATLANTA, GEORGIA.

CHIEF, COMMUNICABLE OISEASE CENTER CHIEF, EPIOEMIOLOGY BRANCH ACTING CHIEF, STATISTICS SECTION CHIEF, SURVEILLANCE SECTION

EOITOR: MMWR

JAMES L. GOOOARO, M.O. A.O. LANGMUIR, M.D. IOA L. SHERMAN, M.S. D. A. HENOERSON, M.O.

O.J.M. MACKENZIE, M.B., F.R.C.P.E.

IN AODITION TO THE ESTABLISHED PROCEOURES FOR REPORTING MORBIOITY AND MORTALITY, THE COMMUNICABLE DISEASE CENTER WELCOMES ACCOUNTS OF INTERESTING OUTBREAKS OR CASE INVESTIGATIONS WHICH ARE OF CURRENT INTEREST TO HEALTH OFFICIALS AND WHICH ARE DIRECTLY RELATED TO THE CONTROL OF COMMUNICABLE DISEASES. SUCH COMMUNICATIONS SHOULD BE ACORESSED TO:

THE EDITOR MORBIDITY AND MORTALITY WEEKLY REPORT COMMUNICABLE DISEASE CENTER ATLANTA, GEORGIA 30333

NOTE: THE DATA IN THIS REPORT ARE PROVISIONAL AND ARE BASED ON WEEKLY TELEGRAMS TO THE COC BY THE INDIVIDUAL STATE HEALTH DEPARTMENTS. THE REPORTING WEEK CONCLUDES ON SATURDAY; COMPILED DATA ON A NATIONAL BASIS APE RELEASED ON THE SUCCEEDING FRIOAY.
